# **Entrusted Loans: A Close Look at China's Shadow Banking System**

## **Abstract**

We perform transaction-level analyses of an increasingly important type of shadow banking in China—entrusted loans. Using a sample of listed firms that are subject to mandatory disclosure requirement for this type of activity, we examine the lender, borrower and loan characteristics. We find entrusted loans increase when the official credit is tight and therefore are a market solution to credit shortage. Lenders either pursue short-run profits (when making non-affiliated loans) or support affiliated parties (when making affiliated loans). Although the two types of loans differ significantly in their average interest rate levels, the pricing of both incorporates fundamental and informational risks. Finally, stock market reactions suggest that both affiliated and non-affiliated loans are fair-compensated investments.

**Keywords:** shadow banking, entrusted loans, credit shortage

## 1. Introduction

Shadow banking involves financing activities that are not subject to regulatory oversight. The shadow banking system is vast in size and is believed to have contributed significantly to the global financial crisis of 2007-2012.<sup>1</sup> It is a major challenge to understand how the system works and what roles it plays, especially in emerging markets and developing economies.

Shadow banking is particularly prevalent in China after a drastic increase in the last decade and there is no sign the growing trend will end soon. According to a Moody's report (2013), by the end of 2012, the total value of shadow banking products in China is 39% of its GDP; and the annual growth rate of these products during 2010-2012 is 32% per year.<sup>2</sup> Both demands and supplies for such alternative financing are plentiful. On the one hand, official financing (such as bank loans and stock and bond markets) is restricted for many firms, including small- and medium-sized state-owned companies, as well as the majority of private-owned firms (Song, Storesletten and Zilibotti 2011 and the references therein, the Moody's report 2013). On the other hand, investors lack sound investment channels due to interest rate control on deposits and the stagnant domestic stock market performance. Both reasons help fuel the growth of shadow banking.

Proponents see shadow banking as an innovation that enriches the economy's financing channels and contributes to a more market-oriented financial system. Critics, however, are concerned that it may lead to higher debt levels and less transparent debt that may impose a key risk to the stability of China's financial system and economy. Regulators trying to weigh the benefits and risks have not come to consensus on how and to what extent to regulate this booming financial sector (see Wei and Davis, 2014).

---

<sup>1</sup>A conservative estimate is 25% of the global financial system, based on "Global Shadow Banking Monitoring Report 2012" by the Financial Stability Board set up by the Group of Seven developed nations.

<sup>2</sup> The Moody's report differentiates core and broader shadow banking activities. The numbers quoted are for the core measure (hence the total value is more conservative).

Researchers worldwide have also debated about the role of shadow banking. Allen, Qian and Qian (2005) argue that alternative financing channels and governance mechanisms support the growth of the private sector in China. Fisman and Love (2003) document that in countries with weaker financial developments, trade credit serve as an alternative financing method and industries dependent on trade credit grow faster. In contrast, Cull, Xu and Zhun (2009) argue that redistribution of bank loans via trade credit was not a major contributor to China's explosive growth. Ayyagari, Demirgüç-Kunt and Maksimovic (2010) find that in China, firms with bank financing grow faster than similar firms without bank financing, and thus question the conclusions of Allen, Qian and Qian (2005). These studies rely on either aggregate summary statistics at the economy or industry level, or survey data voluntarily provided by firms. This paper instead will use loan-level data from listed firms that are under mandatory disclosure requirements. Not only is the information more detailed and of more depth, but also the sample is free of the selection problem that is common to survey data.

Our study focuses on an increasingly important type of shadow banking in China, i.e., the *entrusted loans*. Shadow banking in China has various forms, which are very different from the typical forms in the US such as money market funds or hedge funds. According to Exhibit 1 in the Moody's 2013 report, entrusted loans constitute the largest component of the core shadow banking activities in China (32% of the total RMB size). The other important forms include: 17% in informal lending, 15% in trust loans, 14% in wealth management products, and 11% in credit by financial guaranty companies.<sup>3</sup>

---

<sup>3</sup> Informal lending involves loans between private entities with no payment agents. Trust loans are loans made by trust companies. The trust companies in turn structure these loans into trust schemes or wealth management products and sell them to investors. Wealth management products (excluding entrusted or trust loans as underlying assets) are asset backed securities sold to investors. Underlying assets include bonds, interbank placements, and discounted bills. Banks can be either the entity that structures them or distributor, or both. Guaranty companies provide a guarantee service to borrowers with poor credit profiles to support their bank/trust loans or wealth management issuances.

Entrusted loans are loans made by a non-bank party (e.g., an industrial firm, or an entity sponsored by a local government, or a private equity fund) to another, using a bank as a servicing agent. The bank earns a fee for its service, but does not bear the risk of the investment. According to China's central bank, the total size of entrusted loans increased from RMB 60 billion in 2003 to RMB 2,547 billion in 2013.<sup>4</sup> In 2013, they comprise 14.7% of the country's total financing amount, including bank loans and capital market financing.<sup>5</sup>

Our study focuses on entrusted loans made by publicly traded firms since they are required to disclose these loans. It is uncommon in other parts of the world that non-financial firms engage in making loans since they typically lack a comparative advantage in doing so. It is an interesting question why the phenomenon exists in China.

We manually collect loan information from public firms' annual reports and interim announcements. Our sample includes 1,107 firm-year observations and 2,995 loan transactions during 2004-2013.

We examine four sets of research questions: (1) What kinds of firms tend to make entrusted loans? What motivates them to allocate funds in areas other than their main businesses? (2) Who are the borrowers? Are these entrusted loans likely to allocate capital in certain types of industries? Do they help ease the segmentation of the official financing system, or on the other hand, channel more funds into the red-hot real estate market and help fuel the housing bubble which is now a big concern in China? (3) Are these loans economic- and information-based? In other words, are they priced commensurate with their risk levels? Further, can the price of a loan (i.e., the interest rate) predict the future loan performance (i.e., the likelihood of default)? (4) Do these loans create or destroy value for the shareholders of the lending firms?

---

<sup>4</sup> The exchange rate between USD and RMB changes over time. One USD is worth RMB 8.28, 8.19, 7.97, 7.60, 6.95, 6.83, 6.77, 6.46, 6.31 and 6.20 by the end of each year during 2004-2013, respectively.

<sup>5</sup> The central bank collects data from banks that intermediate these loans. According to practitioners, underreporting is common. Hence these numbers tend to underestimate the real size of the entrusted loans.

We find lenders of entrusted loans tend to be large firms with high cash holdings. These firms, due to their public status and large size, have privileged access to official financing and cheaper capital, and are therefore in an advantaged position to lend to less privileged firms. The volume of these loans increase when credit is tight, measured by the inter-bank offer rate. This suggests that entrusted loans are a form of market-based response to credit shortage.

Our sample contains two types of entrusted loans: affiliated and non-affiliated loans. Most affiliated loans are made by a parent firm to a subsidiary, and some are between a customer and a supplier or between partners of joint ventures. Non-affiliated loans are between two parties without either type of relationship above. Examining the *lender characteristics* suggests different motives behind these two types of loans. Lenders of affiliated loans are more likely to be high-profitability firms and state-owned enterprises,<sup>6</sup> and they have often raised new debt before they make the entrusted loans. In contrast, lenders of non-affiliated loans tend to have low profitability and low growth rates. The evidence suggests that firms use non-affiliated loans as an alternative investment channel to their main businesses; whereas lenders make affiliated loans to support a subsidiary or to build a relationship with a customer or supplier.

The majority of loans in our sample are affiliated loans (80% in terms of the number of loans, and 92% in terms of RMB amount). Although non-affiliated loans are more likely to fund the real estate and construction industry, the majority of the loans are made within industries and therefore do not disproportionately flow into the real estate and construction industry.

Next, we examine the *loan characteristics*. Non-affiliated loans command much higher interest rates than affiliated loans: the mean interest rates are 13.9% for non-affiliated loans and 6.4% for affiliated loans; the mean *adjusted interest rate* benchmarked against the official bank loan rate is 7.9% vs. 0.3%. They also tend to have shorter maturities, and are more likely

---

<sup>6</sup> State-owned enterprises (SOEs) tend to have better access to official financing compared to private firms.

to have collateral and a third-party guarantee. This is consistent with the previous observation that non-affiliated loans are used as an alternative investment channel and therefore are pursuing immediate profits. The affiliated loans are used to support a subsidiary or a business partner. To examine whether these loans are economic- and information-based, we ask two questions: (1) Are the loans priced based on the borrowers' fundamental and informational risks? (2) Can the prices of the loans predict future loan performance, i.e. the likelihood of default? Empirical evidence suggests that the pricing of both affiliated and non-affiliated loans depend on fundamental and informational risks. The adjusted interest rate increases if the borrower is in a high-risk industry, and decreases when the lender is in the same industry or located in the same city as the borrower (hence the information asymmetry between the two parties are lower). This effect of informational risk is more pronounced for non-affiliated loans. Moreover, for non-affiliated loans, the likelihoods of default and extension increase with their interest rates, confirming that the pricing of these loans are risk-based.<sup>7</sup>

Finally, we examine whether entrusted loans create or destroy value to lending shareholders by examining the stock price reaction upon the announcements of these loans. Although the affiliated loans tend to charge below-market interest rates, it is not clear whether they are inefficient subsidies between affiliated parties, or a form of investment in the borrowing firm by the lender in hope for long-run returns from equity investment or for stable supplies of raw materials. We find announcement returns for affiliated loans are not significantly different from zero, suggesting that these loans do not destroy value. We find non-affiliated loans are fairly-compensated investments as well, although investors react negatively the first time a firm announces such a loan and reveals to the market that it lacks good investment opportunity in its main business.

---

<sup>7</sup> Although loan extensions can be voluntary by lenders, most cases are due to borrowers' inability to pay back on time, according to interviews with practitioners.

This study is the first large-sample transaction-level analysis of China's shadow banking system. We document evidence that entrusted loans made by public firms are market solutions to credit shortage. The pricing of these loans are economic- and information-based. Although lenders can have different purposes (making profits or supporting affiliated businesses), the key factor is that lenders take advantage of their privileged access to the official financing system to provide credit to less privileged firms.

The rest of the paper is organized as follows. Section 2 describes the sample and the data. Section 3 investigates lender characteristics. Section 4 explores loan characteristics and what determines the loan pricing. Section 5 examines the wealth effects of these loans. Section 6 concludes.

## **2. Sample and Data**

We manually collect our sample and data by conducting keyword-search for different variations of "entrusted loan" in the annual reports and interim announcements of public non-financial firms. We identify the lender and the borrower, and record loan characteristics such as the loan amount, the interest rate, the maturity, and whether the two parties are affiliated. We then obtain additional information about the lenders from Wind Database, which provides accounting and return data for listed firms. In our sample, the majority of borrowers (99%) are non-listed firms, so we have limited information about them. We identify a borrower's industry, headquarters location and whether it is an SOE based on information provided by the lender or by our own manual search.

Our sample includes 2,995 entrusted loans made by 498 unique firms that correspond to 1,107 firm-years during 2004-2013. In this period, the entire public market of China has 2,467 unique non-financial firms that correspond to 18,003 firm-years.

Table 1 reports by year the number of listed firms that make entrusted loans, the number of loans, and the total loan amount. We observe a fast growing trend of entrusted loans. The number of firms making entrusted loans increases from 55 in 2004 to 220 in 2013. The total amount of loans takes an over-ten-fold leap from 12.6 billion RMB in 2004 to 219.2 billion RMB in 2013. In 2013, our sample accounts for about 10% of the aggregate amount of entrusted loans reported by the central bank.

### **3. The Lenders**

We investigate what types of firms make entrusted loans. What motivates them to lend instead of investing in their main businesses? What differentiates firms that make loans from those that do not? In addition, we also compare lenders of affiliated loans with those of non-affiliated loans.

Table 2 reports the descriptive statistics of lender characteristics. The first two columns show the mean values of variables for firm-years with and without entrusted loans. Firms with loans are much larger than those without in terms of the asset value at the beginning of the year (18.1 billion vs. 5.8 billion). Firms with loans also have higher profitability measured by return on assets (ROA) (7.6% versus 6.9%), and a larger amount of recently issued debt as a percentage of average assets (7.8% versus 4%). These differences are all statistically significant at the 1% level. These financial characteristics of lending companies suggest that larger firms with higher profitability and more external financing are more likely to provide entrusted loans. Moreover, the first two columns also show that state-owned enterprises (SOEs) and firms in the real estate industry are more likely to engage in lending. As high as 74% of lenders are SOEs whereas the ratio is 55% for firms without loans. The percentage of lenders and non-lenders in the real-estate industry is 10% and 8% respectively.

We then examine lenders of non-affiliated and affiliated loans separately in Columns (3) and (4) in Table 2. The number of firm-year observations with affiliated loans is more than twice those with non-affiliated loans; therefore it is not surprising that the differences between lenders and non-lenders are driven by those making affiliated loans. More importantly, the two types of lenders have significant differences. Compared to firms making non-affiliated loans, firms making affiliated loans have more assets (a mean of 21.0 billion RMB vs. 10.6 billion RMB), higher sales growth (26.5% vs. 18%), higher debt ratios, more recently issued debt (8.7% vs. 5% of total assets), are more likely to be SOEs (80% vs. 57%) and have a higher percentage in the real estate business (12% vs. 7%).

Similarly to lenders of affiliated loans, although to a lesser degree, firms making non-affiliated loans tend to be larger (i.e. more assets) than non-lenders. Unlike lenders of affiliated loans, firms making non-affiliated loans do not differ significantly from non-lenders in ROA, new debt, and the likelihood of being an SOE or a real-estate company. In contrast to lenders of affiliated loans, they actually have a lower growth rate and less debt than non-lenders.

We then run multivariate regressions to explore the determinants of the loan decisions. In addition to the firm characteristic variable listed in Table 2, we also include a measure for the condition of the economy, namely the interbank offered rate, which measures the overall availability of liquidity and credit in the economy. We obtain daily data on the interbank offered rate from the China Center for Economic Research (CCER) Database, and use the yearly average in the regression. The yearly averages for our sample periods are 2.13%, 1.31%, 1.86%, 2.15%, 2.30%, 1.12%, 1.71%, 3.28%, 2.80%, 3.37%, respectively.

Table 3 reports the results of two types of regressions. In the first three columns, we report logit regressions using *Loan dummy* (an indicator that there is an entrusted loan for the firm-year) as the dependent variable. For each regression, we include both firm-years with and

without loans. The loan sample includes firm-years with both types of loans, non-affiliated loans only and affiliated loans only, respectively, in Columns (1)-(3).

Consistent with the univariate results in Table 2, different factors may impact firms' decisions to make affiliated and non-affiliated loans differently. Nonetheless, two factors stand out in that they have significant impact on the likelihood of a loan, and that their effects on both types of loans are similar. The coefficients on  $\ln(\text{assets})$  and *interbank offered rate* are significant and positive in both Columns (2) and (3), suggesting that larger firms are more likely to make both affiliated and non-affiliated loans, and that there are more of these loans when the credit is tight in the economy. For the economic significance of the effects, given all other explanatory variables are at their means, when *interbank offered rate* increases from its 25th percentile to 75th percentile, the probability of making a non-affiliated loan increases from 1.15% to 1.94%, and the probability of making an affiliated loan increases from 2.61% to 3.91%.

Several factors have impact on the decision to make affiliated loans, but not on non-affiliated loans. That is, the likelihood of affiliated loans increases if the firm has higher profitability (measured by ROA), if the firm has raised more debt recently, if the firm is an SOE, and if it is in the real-estate industry. For economic significance, given all other explanatory variables are at their means, when *ROA* increases from its 25th percentile to 75th percentile, the probability of making an affiliated loan increases from 2.87% to 3.24%, and when the *change of debt* increases from its 25th percentile to 75th percentile, the probability of making an affiliated loan increases from 2.88% to 3.25%. Similarly, keeping other variables at their means, the probability of making an affiliated loan is 2.03% for a non-SOE firm and 4.21% for an SEO firm. The probability of making an affiliated loan is 3.00% for a non-real estate firm and 3.75% for a real estate firm.

The likelihood of non-affiliated loans, on the other hand, decreases with the firm's sales growth rate and its debt ratio. If *sales growth* increases from its 25th percentile to 75th percentile, given all other explanatory variables are at their means, the probability for a firm to make a non-affiliated loan decreases from 1.50% to 1.33%. When *Debt/asset* increases from its 25th percentile to 75th percentile, the probability for a firm to make a non-affiliated loan decreases from 1.88% to 1.10%.

In addition to the logit regressions, we also estimate Tobit regressions using the ratio of the amount of loan to total assets as the dependent variable, using zero as the lower limit. The last three columns of Table 3 present results of Tobit regressions. These results are consistent with those of the logit regressions. If *interbank offered rate* increases by one standard deviation (0.76%), the loan ratio (loan relative to assets) increases by 2.05 percentage points for non-affiliated loans and 1.29 percentage points for affiliated loans.

For non-affiliated loans, if *sales growth* increases by one standard deviation (56.9%), the loan ratio decreases by 1.50 percentage points. If a firm's debt ratio (the firm's total debt relative to assets) increases by one standard deviation (16.9%), the loan it makes (relative to assets) decreases by 2.94 percentage points. For affiliated loans, if *ROA* increases by one standard deviation (8.77%), the loan ratio increases by 0.98 percentage point. If the change of debt level increases by one standard deviation (15.7%), the loan ratio increases by 1.10 percentage points. The loan ratio for an SOE lender is 4.46 percentage points higher than that for a non-SOE lender, and for a real estate lender is 3.31 percentage points higher than that for a non-real estate lender.

Our sample period includes the recent global financial crisis. In 2009, China went through its own version of "Quantitative Easing" and injected four trillion RMB into its banking system. To make sure our results are not driven by such an unusual period, we estimate the logit and Tobit regressions excluding year 2009 (untabulated) and our results are robust.

In summary, the likelihoods of both types of loans increase with the lender's size and when credit is tight in the economy. However, there are important differences between the two types of lenders. Lenders of affiliated loans tend to be SOEs, have high profitability, and have raised new debt recently. These characteristics suggest that they are in good positions to support their affiliated parties. In addition to good profits, they probably have privileged access to various sources of capital and do not mind raising new capital to finance the loans. On the other hand, lenders of non-affiliated loans tend to have lower growth rates and therefore may use the loans as a new channel to generate profits and growth. They also have less debt and do not raise new debt before making the loan.

#### **4. The loans**

We now examine the entrusted loans at the transaction level, as opposed to the firm-year level. Out of the 2,995 loans in our sample, we can identify the borrower and loan characteristics in 2,960 cases.

##### *4.1 Distribution of lending and borrowing industries*

Table 4 presents RMB amount of entrusted loans by lender and borrower industries. Lenders from the coal and mining industry make the largest amount of loans (249 billion RMB, or 36.0% of total amount), followed by industries of utilities (21.2%), real estate and construction (7.7%), auto and auto parts (7.1%), and transportation (5.6%).

Interestingly, the same 5 industries also receive the largest amounts of loans: coal and mining (37.2% of total amount), utilities (19.0%), real estate and construction (14.4%), auto and auto parts (6.7%), and transportation (4.6%). This is because many loans are within-industry loans (Table 5 shows that such loans are 67% of the sample).

If we calculate the net lending amount (lending minus borrowing amount) for each industry, only three industries have an absolute value larger than 10 billion RMB. The two industries that lend out the most are utilities (15.0 billion) and commerce (12.4 billion). The industry that receives the most net borrowing is real estate and construction (46.6 billion). This is not surprising given the importance of real-estate and construction industry in China's economy. Based on a recent IMF report on China (IMF 2014), "it [the industry] directly accounted for 15 percent of 2012 GDP, a quarter of fixed-asset investment, 14 percent of total urban employment, and around 20 percent of bank loans" (page 22). Benchmarked against these numbers, the amount of entrusted loans going to the real-estate and construction industry is not high (the ratio of the industry's borrowing (or net borrowing) to total loan amount is 14.4% (6.7%)). In particular, the percentage of entrusted loans to the industry is lower than that of bank loans. Moreover, the rest of the loans have a reasonably diverse distribution among over twenty broadly-defined industries.

The above conclusion, however, is driven by affiliated loans, which constitute the majority of our sample. For non-affiliated loans, a much larger portion of money flows into the real estate and construction industry. The industry's total borrowing is 21.9 billion RMB, which is 46% of the total amount of the non-affiliated loans and almost 10 times the total borrowing of the second largest borrowing industry—the transportation industry. The net borrowing amount of the real estate and construction industry is 17.7 billion RMB, which is 37.2% of the total amount of non-affiliated loans.

Our study focuses on entrusted loans made by listed firms. It is worth noting that in recent years (starting from 2009, the year of the large stimulus package), another type of lender—private equity funds—has gained an increasing market share of entrusted loans. Although we do not have direct data on this group of loans, our understanding is that these loans are driven by the pursuit of immediate profits, based on interviews with practitioners. Therefore they

have characteristics associated with non-affiliated loans—most strikingly, they command high interest rates and are more likely to flow into restricted industries such as the real estate and construction industry.

In January 2015, the China Banking Regulatory Commission (CBRC) proposed new rules on entrusted loans. One important change is that debt-financed funds are prohibited from making entrusted loans, which aims to exclude these private equity players from this market. It remains to be seen whether this will be included in the final version of the new regulations and whether it will achieve the intended results.

#### *4.2 Summary statistics of loan characteristics*

Table 5 presents summary statistics for loan, borrower and lender characteristics. The most striking difference between affiliated and non-affiliated loans is in the interest rate: affiliated loans command about half the rate of that for non-affiliated loans. The average interest rate is 6.4% for affiliated loans vs. 13.9% for non-affiliated loans. We calculate *adjusted interest rate* as the difference between the loan rate and the official lending rate specified by the central bank categorized by maturity. The average adjusted rates for affiliated and non-affiliated loans are 0.3% and 7.9%, respectively. In other words, affiliated loans charge about the same rate as official bank loans. In China, other than a small group of privileged firms (i.e., the large SOE firms), the market cost of borrowing for most firms is much higher than the official bank loan rate (Song, Storesletten, and Zilibotti 2011). Hence the low interest rate indicates that affiliated loans are used to support a subsidiary or to build a long term relationship with a supplier or a customer. For example, in 2006, SAIC Motor, the largest listed auto company in China A-share stock market, provided a five-year low interest loan of 94 million RMB to Ningbo Huaxiang Electronic, a major supplier for automotive components. SAIC Motor stated in its annual report that the purpose of the loan was to ensure the supplier to provide quality

components on schedule. Nonetheless, whether these loans with below-market rates are inefficient subsidies or long-term investments is an open question.

Compared to non-affiliated loans, affiliated loans also tend to be larger (with a mean of 269 million RMB vs. 81 million RMB), longer maturity (18 months vs. 12 months), are less likely to need collateral and guarantee (11% vs. 74%). In addition, only affiliated loans may be used to retire earlier debt (3% vs. 0%). Affiliated loans are also more likely to be used for specified projects (6% vs. 3%). These findings are consistent with prior studies that borrowers with relationship with lenders receive favorable terms such as greater credit availability and lower collateral requirements (Petersen and Rajan 1994, Berger and Udell 1995).

Lenders of affiliated loans are more likely to be SOE firms (83% vs. 64%). Since a SOE's subsidiaries tend to be SOE firms too, the proportion of borrowers of affiliated loans being SOEs is also high (78%). In contrast, the percentage of SOE borrowers for non-affiliated loans is much lower (20%). This suggests that it is the least privileged firms—the small non-SOE firms—that are taking entrusted loans from non-affiliated parties at market interest rates that are much higher than the official bank loan rates. Another noteworthy difference is that borrowers of affiliated loans are much less likely to be in the real-estate industry (16% vs. 46%). The percentages of lenders in the real-estate industry are low for both types of loans (9% for affiliated loans and 5% for non-affiliated loans).

Moreover, a high percentage of affiliated loans (81%) are made within industry. This is not surprising since the loans are either between parent firms and subsidiaries, or between customers and suppliers. The proportion of same-industry loans for non-affiliated parties is low (10%). In addition, non-affiliated loans are much more likely to be made to same-city borrowers (51%) than affiliated loans (36%).

#### *4.3 Do loan rates depend on risk?*

In this section, we investigate what determines the pricing of the entrusted loans, i.e., the interest rate. Allen et al. (2013) argue that constructive (information-based) informal financing plays an important role in the financial market of China. We are interested to see for the entrusted loans in our sample, whether the pricing depends on the borrower's fundamental and informational risks.

Since most (98.7%) of the borrowers are not publicly traded firms, we have limited information about them. We obtain the borrower's name from the lenders' disclosure, and manually collect information about its industry, location and whether it is an SOE, if such information is missing from the lenders' disclosure.

To measure a borrower's business risk, we consider its industry risk and whether the firm is an SOE. We use three variables to measure industry risk: (1) *borrower industry median return volatility*, computed as the median of the standard deviations of daily returns for firms in the borrower industry during the year before the loan is made; (2) *borrower industry sales growth dispersion*, computed as the standard deviation of sales growth of firms in the borrower industry during the year before the loan is made; (3) *real estate borrower*, a dummy variable equal to one if the firm is in the real estate and construction industry. Firms in the real estate and construction industry are often considered to be of high risk, as many worry about the bubble in the housing market (e.g., Wu et al., 2012). In addition, despite the general increase in housing prices during our sample period, firm performance in the industry varies widely. For example, its average (across years) industry sales growth dispersion is 106% and is the highest among all the industries, and its average (across years) industry median return volatility is 3.09% and ranks as No.6 among all the industries. The correlation of *real estate borrower* and *borrower industry sales growth dispersion* is 0.70, and the correlation of *real estate borrower* and *borrower industry median return volatility* is 0.17. At firm-level, a firm tends to have lower debt risk if it is a SOE for two things: one, SOEs tend to be larger than private

firms; second, SOEs typically have better access to official financing and therefore have higher abilities to meet their debt obligations.

We use two variables to measure the extent of information asymmetry between the borrower and the lender: a dummy variable indicating whether they are in the same city, and a dummy indicating whether they are from the same industry. Prior researches on bank loans document that banks located closer to borrowing firms incur lower information production and monitoring costs (e.g. Degryse and Ongena 2005, Mian 2006). It is also reasonable to think that lenders understand borrowers from the same industry better.

Table 6 presents univariate-analysis evidence of the impact of these risk measures on interest rates. Specifically, we compare the mean adjusted interest rates between subsamples of loans differing in these risk measures. For dummy variables, we compare subsamples with and without the respective characteristic. For continuous variables, we compare subsamples with above-median vs. below-median values of the respective risk measure.

Consistent with the informational risk hypothesis, the results show that for non-affiliated loans, borrowers located in the same city as lenders pay lower interest rates (the mean adjusted interest rate is 7.2% vs. 8.6% if the two parties are not in the same city, the difference statistically significant at the 1% level). For affiliated loans, the rate is also lower for same-city loans but the difference is much smaller (0.2% vs. 0.4%, the difference significant at the 10% level). In other words, for affiliated loans, geographic distance is not as important a factor compared to non-affiliated loans. It is plausible that lenders have good information about affiliated parties regardless whether they are from the same city. In addition, we recall that the percentage of same-city loans is higher for non-affiliated loans. This is consistent with the notion that firms are more willing to lend to a non-affiliated firm if it is in the same city hence presents lower informational risk.

Also consistent with the informational risk hypothesis, the interest rate is lower if both parties are from the same industry. In our sample, 81% of affiliated loans and 10% of non-affiliated loans occur between two firms in the same industry. The high proportion of within-industry loans for affiliated loans is determined by the nature of the ownership or business affiliations. For non-affiliated loans, within-industry loans command lower interest rates (6.0% vs. 8.1%). For affiliated loans, within-industry loans also have lower adjusted interest rates (0.1% vs. 1.3%). The same-industry factor seems to have a much larger impact on the interest rate than the same-city factor for affiliated loans, but again the impact is smaller than that for the non-affiliated loans.

Table 6 also reports the mean adjusted interest rate conditional on whether the borrower is a SOE. In China, SOEs usually enjoy better access to bank loans as major banks are also state-owned. The majority of the lenders of both affiliated loans and non-affiliated loans are SOEs (83% and 64%, respectively), but for non-affiliated loans, only 20% borrowers are SOEs (vs. 66% for affiliated loans), suggesting borrowers of non-affiliated firms are underprivileged firms that have restricted access to official financing. We observe that non-SOE borrowers pay significantly higher adjusted interest rates than SOE borrowers (8.8% vs. 4.2% for nonaffiliated loans, and 0.7% vs. 0.2% for affiliated loans). This reflects non-SOE firms' higher firm risk (they are often smaller firms) as well as their lower bargaining power due to their restricted access to official financing.

When looking at the three measures of borrower industry risk, we find a similar pattern—that is, risky borrowers pay higher interest rate. Table 6 shows that real-estate borrowers pay higher adjusted interest rates than non-real estate borrowers (9.5% vs. 6.6% for non-affiliated loans, and 2.8% vs. -0.2% for affiliated loans); borrowers with above-median industry return volatility pay higher rates than those with below-median volatility (9.0% vs. 6.7% for non-affiliated loans, and 0.5% vs. 0.1% for affiliated loans); borrowers with above-median industry

sale growth dispersion pay higher rates than those with below-median dispersion (8.5% vs. 6.8% for nonaffiliated loans, and 0.8% vs. -0.2% for affiliated loans). All the differences are statistically significant.

Next we estimate multivariate regressions to see whether these borrower risk measures explain the variation in interest rate after controlling other factors. The dependent variable is the adjusted interest rate. For control variables, we include loan and lender characteristic variables as those listed in Table 5. In addition, for affiliated loans, we include two additional variables: *ownership* which measures the lender's equity ownership in the borrower, and *trade relationship* which is a dummy variable equal to one if the borrower is a customer, a supplier, or a joint-venture partner of the lender.

Table 7 reports the regression results for the samples of non-affiliated loans (Panel A) and affiliated loans (Panel B) separately. The results suggest that the interest rate increases with borrower's risk. For both types of loans, the coefficients on all three borrower industry risk measures—*borrower industry median return volatility*, *borrower industry sales growth dispersion* and *real estate borrower*—are all positive and statistically significant at the 1% level. If the borrower is in the real-estate industry, the adjusted rate is higher by 2.5 percentage points for non-affiliated loans and 2.2 percentage points for affiliated loans. A one-standard deviation increase in the *industry sales growth dispersion* leads to a 0.9 percentage-point rate increase for non-affiliated loans and 0.6 percentage-point rate increase for affiliated loans. A one-standard deviation increase in the *industry volatility* leads to a 1.9 percentage point rate increase for non-affiliated loans and 0.7 percentage-point rate increase for affiliated loans. The coefficient on *SOE borrower* is significantly negative for non-affiliated loans. If the borrower is a SOE, the interest rate on average is lower by 3.5 percentage points. The coefficient on *SOE borrower*, however, is non-significant for affiliated loans, possibly because affiliated parties receive favorable rates regardless of their SOE status.

Informational risk also has positive impact on the interest rate of both types of loans, and the effects are stronger for non-affiliated loans. If located in the same city as the lender, a borrower on average pays a lower interest rate (0.8–1.5 percentage points lower for non-affiliated borrowers and 0.4–0.5 percentage points lower for affiliated borrowers). A borrower in the same industry as the lender is also charged a lower rate (2.1–2.6 percentage points lower for non-affiliated borrowers and 0.5–1.1 percentage points lower for affiliated borrowers).

For both types of loans, the adjusted interest rate is negatively related to the loan maturity and positively related to the use of collateral or guarantee. This suggests that these contract terms are used simultaneously as complements to each other to control the investment risk. That is, in addition to charging higher rates, lenders will limit their risk exposure by forcing riskier borrowers to take shorter-term loans and to secure the debt with collateral or a guarantee. This observation is consistent with existing studies on bank loans (e.g. Flannery, 1986; Dennis et al., 2000). The effects of maturity and use of collateral/guarantee are stronger for non-affiliated loans than that for affiliated loans.

In summary, Table 7 shows that the pricing of both non-affiliated loans and affiliated loans take into account the borrowers' fundamental risk and information risk. Nonetheless, the rates of non-affiliated loans are much more sensitive to informational risk (whether the borrower is in the same city or same industry as the lender). As there is more information asymmetry between non-affiliated lenders and borrowers, being in the same city or industry helps in greater extent to mitigate the information problem. A SOE borrower also provides stronger assurance to non-affiliated lenders.

#### *4.4 Loan rate and loan performance*

As an alternative way to test whether the pricing of entrusted loans incorporates risk in an efficient way, we examine whether the interest rate can predict the future performance of loans.

That is, if riskier loans command higher rates, then higher rates should be associated with higher likelihoods of default or other payback difficulty.

We manually collect information about the outcome of entrusted loans from firms' annual reports and interim announcements. The lending firm needs to make disclosure in its annual report or make an announcement if a loan is delinquent, overdue or extended. By interviewing practitioners, we learn that loan extensions are usually due to borrowers having difficulty of paying back on time. We include 2,243 loans in this analysis that are originally due by the end of year 2013 (1782 affiliated loans and 461 non-affiliated loans).

Panel A of Table 8 presents the number of incidences of loan delinquency, overdue and extension by 2013 for our sample loans, and the distribution of these cases between affiliated and non-affiliated loans. There are a total of 194 such cases, 130 for affiliated loans and 64 for non-affiliated loans. Thus, the percentage of problematic affiliated loans is smaller than that of non-affiliated loans (7.3% vs. 13.9%). When there is a problem, a higher proportion of affiliated loans are extended (88%) than non-affiliated loans (70%). Panel A also reports the average loan amount for each type of problematic loans. The average amounts for delinquent, overdue and extended loans are 51, 99, and 139 million RMB, respectively. The average amount for non-problematic loans is 229 million RMB. This seems to suggest two things: (1) lenders tend to lend smaller amounts to riskier borrowers; and (2) when large amounts are involved, lenders may have more incentive to extend the loans.

Panel B of Table 8 compares the adjusted interest rate between problematic and non-problematic loans. For the subsample of non-affiliated loans, the ex ante interest rates are higher for problematic loans than for non-problematic loans. The average adjusted interest rate for loans that are overdue and extended are 10.2% and 10.9%, respectively. In contrast, the average adjusted rate for non-problematic loans is 7.8%. The difference in rate is statistically significant between each group of problematic loans and the non-problematic loans.

By contrast, such differences are absent for affiliated loans. The average adjusted interest rate for loans that are delinquent, overdue, extended are 0.5%, -0.1%, and 0.6%, respectively. None of them is significantly different from the rate for non-problematic loans, which is 0.3%. This seems to suggest that the pricing of the affiliated loans, although taking into account borrowers' risk to some extent, does not incorporate risk in a full and efficient way.

We then estimate multivariate logit regressions to examine the determinants of loan performance. The dependent variable is a dummy equal to 1 if the loan is delinquent, overdue or extended. Our main variable of interest is the adjusted interest rate. We also control for other loan characteristics, borrower characteristics and lender characteristics as those in Table 7. For borrower industry risk, we use the industry median return volatility. Main results are robust if we use industry sales growth dispersion or real estate borrower dummy.

Table 9 reports the regression results for non-affiliated loans (in Column 1) and affiliated loans (in Column 2). Consistent with the univariate results, Column 1 of Table 9 shows that for non-affiliated loans, the adjusted interest rate is positively related to the likelihood of the loan being extended, overdue or delinquent. The coefficient on the adjusted rate is 0.15 and significant at the 1% level. Given all other explanatory variables are at their means, when *Adjusted interest rate* increases from its 25 percentile to 75 percentile, the probability of delinquent, overdue or extended increases from 4.5% to 13.9%. Thus the interest rate of non-affiliated loans can predict future loan performance. This is consistent with the notion that riskier loans are charged with higher interest rate *ex ante* and end up with worse performance *ex post*.

Furthermore, Column 1 shows that after including the interest rate, borrowers' characteristics mostly have no predicting power for loan performance. This indicates that the interest rate has incorporated the risk information contained in these variables. Thus non-affiliated loans are priced in a fairly efficient way. One exception is *same-city dummy* that has

a significantly negative coefficient, suggesting that likelihood of problematic loans is smaller of the lender and the borrower are in the same city. In untabulated results, we observe that 7.5% of same-city non-affiliated loans turn out to be problematic whereas the ratio more than doubles for non-affiliated loans across cities (20.8%). This is consistent with the notion that there is less information asymmetry if lenders and borrowers are in the same geographical location. When in the same city, a lender is better at either screening borrowers, or enforcing the loan payment, or both. Although same-city loans receive lower interest rates (Table 7), Table 9 suggests that the interest rate still under-reacts to the information whether the borrower is in the same city as the lender.

Column (2) presents strikingly different results for affiliated loans. The adjusted interest rate has no predictive power for loan performance. This suggests that the pricing of this type of loan does not incorporate risk information sufficiently. Again this is consistent with the notion that affiliated loans are not driven by short-term profits but to support affiliated parties.

## **5. Wealth effects of entrusted loans**

In this section, we analyze the value consequence of the entrusted loans to the lenders. We have shown that non-affiliated entrusted loans charge much higher interest rates than affiliated loans—in particular, the latter type charges rates much lower than the market rate. This evidence alone, however, does not imply that non-affiliated loans create values and affiliated loans destroy values. The lower-than-market rates of affiliated loans can be a form of long-term investments in its affiliated parties, as opposed to inefficient cross-subsidization. For non-affiliated loans, the loans may create value, destroy value, or receive fair compensation depending on whether the interest rates are high enough for the risk.

To address the question whether entrusted loans create value, we examine the stock market reactions to the loan announcement, assuming the market is efficient in incorporating the value

consequence. For this analysis, we focus on the 547 cases (358 affiliated loans and 189 non-affiliated loans) where the lending firms make announcements about the loans before the annual reports. There is a sample selection issue since not all firms make interim announcements. We describe and address this issue in multivariate regressions below. We estimate the cumulative abnormal returns (CARs) around the announcement based on the market model, using the index return of stocks traded on Shanghai and Shenzhen stock exchanges as the market proxy and the trading days [-150, -10] as the estimation period, where day 0 is the announcement day.

We first examine whether the announcement returns are significantly different from zero. If they are not, it suggests that these deals neither create nor destroy value, i.e., they are on average zero-NPV investments. If CARs are significantly positive (negative), there are two possibilities: one possibility is that these loans do create (destroy) values. Alternatively, these loans do not create (or destroy) values, but the fact that the lenders are making these loans can reveal to the market new positive (negative) information about the lenders. To distinguish the value-creation vs. the information-revelation hypothesis, we divide the loans into two groups: firms' first announcements vs. subsequent announcements, depending on whether it is the first time a firm announces such a loan during our sample period. If the abnormal returns are concentrated in firms' first loans, then they are more likely because of information revelation as opposed to value creation. In contrast, the value-creation hypothesis predicts that the abnormal returns should be present in both first and subsequent loans.

Table 10 Panel A presents the mean CARs for affiliated loans and non-affiliated loans separately. We compute CARs for 3 time windows, trading days [-1, 1], [-3, 3] and [-5, 5] around the announcement, where day 0 is the announcement day. The results are consistent for all three CAR measures—the mean CAR is non-significant for affiliated loans, while it is significantly negative for non-affiliated loans. This suggests that affiliated loans neither create

nor destroy value, but instead are zero-NPV investments. Despite their lower-than-market interest rates, investors view them as a form of investment that receives fair compensation in the future, rather than inefficient subsidization. In contrast, the negative CARs for non-affiliated loans suggest that this type of loans either destroy value, or convey negative information about the lender.

For each type of affiliated and non-affiliated loan, we then divide them into firms' first vs. subsequent loan announcements. For affiliated loans, there are no significant differences between the two groups of transactions. For non-affiliated loans, only the first announcements exhibit negative CARs while the subsequent announcements are associated with non-significant and near-zero CARs: the differences between the two groups are all significant at the 5% level. Take the mean CARs around days [-5, 5] for example. The average CAR for all non-affiliated loans is -1.39%, significant at the 10% level. The mean for firms' first non-affiliated loans is -3.78% and significant at the 1% level, whereas the mean for subsequent non-affiliated loans is a non-significant 0.33% (the difference is significant at the 1% level).

The fact that the negative CAR is concentrated in firms' first announcements of non-affiliated loans is consistent with the information-revelation hypothesis. That is, upon learning a firm's making non-affiliated loans, investors realize that the firm lacks good investment opportunities in their main businesses, which is bad news. These loans themselves, on the other hand, do not destroy value, as evidenced by non-significant CARs for subsequent similar transactions.

Next, we estimate multivariate regressions of CARs. We include *a firm's first announcement*—a dummy equal to one if it is the first time announces an affiliated or non-affiliated loan—in the regression as the univariate results show that this is an important factor. In addition, the abnormal returns may also depend on the terms of the loans. So we include  $\log(\text{loan amount})$ , adjusted interest rate, maturity, and the dummy for collateral or guarantee.

We note there is a selection issue in examining the announcement returns since not all firms make such announcements. Instead many of them make the required disclosure in their annual reports, together with other important disclosures, such as earnings announcements. The regulatory requirement on making interim announcements is vague—firms need to make announcements for “material” investments and events, although there is no technical definition for what is considered material. To address this, we investigate whether the choice of loan announcement depends on loan amount and lender characteristics. We then run a two-stage Heckman test, where the first-stage is a logit regression of whether or not a loan announcement is made, and the second-stage is a regression of CARs.

Table 10 Panel B reports the regression of CARs for affiliated and non-affiliated loans. The dependent variable is the 11-day CARs. Results are similar if we use the 3-day or 7-day CARs. We report both the OLS and the Heckman 2<sup>nd</sup>-stage regression results, which yield similar results. For non-affiliated loans, the most important determinant of CARs is the dummy of *a firm's first announcement*. It has a highly significant and negative coefficient, suggesting that firms' first non-affiliated loan announcements are associated with much more negative abnormal returns, which is consistent with the univariate results. We do not find evidence that loan characteristics such as loan amount or interest rate have significant impact on market reactions, consistent with the notion that these loan terms are endogenously chosen. For affiliated loans, the only coefficient significant at the conventional levels is that on *a firm's first announcement* in the OLS regression. The significance disappears in the Heckman regression.

The bottom portion of Panel B displays the results of Heckman's first-stage regressions for affiliated and non-affiliated loans, respectively. For both types of loans, we observe that the likelihood of loan announcements increases with the loan amount, and decreases with the firm size in terms of assets. This makes sense since the larger the loan size relative to the lender's

asset value, the more “material” the transaction is. In addition, for affiliated loans, SOE lenders are less likely to make announcements.

In summary, the results in this section suggest that both affiliated and non-affiliated loans are fairly-compensated investments. Despite the lower-than-market interest rates, affiliated loans do not destroy value. Firms’ first non-affiliated loans reveal lenders’ poor investment opportunities in their main businesses, to which investors respond negatively.

## **6. Conclusions**

We conduct the first large-sample transaction-level study of China’s shadow banking system. Specifically, we examine the entrusted loans made by listed firms. These non-financial firms engage in these loans because they can take advantage of their privileged access to the official financing system (such as bank loans and the stock market) to provide credit to less privileged firms. The likelihood and the amount of entrusted loans increase when credit is tight in the economy. Thus these loans are market reactions to credit shortage.

There are important differences between the two types of entrusted loans – non-affiliated loans and affiliated loans. Lenders of non-affiliated loans suffer low growth rates and hence use the loans as an alternative investment channel to boost their earnings. In contrast, lenders of affiliated loans are highly profitable and use the loans to support their subsidiaries, suppliers, or customers. As a result, they might gain long-term benefit such as returns from equity investment of subsidiaries, stable and quality supplies from suppliers, or stable demand from customers.

Consistent with the different motivations, the average interest rate for non-affiliated loans is about twice that for affiliated loans. Nonetheless, we find evidence that the pricing of both types of loans depends on borrowers’ fundamental and information risks, although the pricing of non-affiliated loans is more sensitive to risk. Moreover, the interest rates of *non-affiliated*

*loans* have predicting power for future loan performance, i.e., the likelihood that a loan is delinquent, overdue or extended increases when the interest rate is high. But the interest rates of *affiliated loans* have no predictive power of future loan performance. This suggests that the pricing of non-affiliated loans incorporate risk more sufficiently than that of affiliated loans.

Finally, our investigation of announcement returns suggests that both affiliated and non-affiliated loans are fairly-compensated investments. Thus, the lower-than-market interest rates of affiliated loans are viewed as a form of investments rather than inefficient subsidization.

Our study focuses on a specific form of shadow banking in China. Other types of shadow banking may have their own unique mechanisms. More research is needed about the roles and functions of different types of shadow banking.

**Table 5 Descriptive Statistics for Entrusted Loans**

The sample includes 2,960 entrusted loans during 2004-2013. The number of non-missing observations for (*adjusted*) *interest rate* and *maturity* are 2,812 and 2,863, respectively. Variables definitions are in Appendix. All RMB values are adjusted to constant year 2013 RMBs. Financial variables are winsorized at 1% and 99%.

**Table 6 Interest Rate of Non-affiliated Loans vs. Affiliated Loans**

This table compares the mean adjusted interest rates between subsamples of loans differing in borrower risk measures. For dummy variables, we compare subsamples with (“yes”) and without the respective characteristic (“no”). For continuous variables, we compare subsamples with high (above-median) vs. low (below-median) values of the respective risk measure. The sample includes 2,812 entrusted loans that have interest rate information during 2004-2013. Variables definitions are in Appendix.

	Non-affiliated loans			Affiliated loans		
	Yes	No	Diff	Yes	No	Diff

## Appendix: Variables Definition

---

<i>A firm's first announcement</i>	A dummy equal to one if it is the first time a firm announces to a (affiliated or non-affiliated) entrusted loan, and zero otherwise
<i>Adjusted interest rate (%)</i>	A loan's interest rate minus the official bank lending rate of same maturity
<i>Affiliated loan</i>	A dummy equal to one if a firm made a loan to an affiliated party, and zero otherwise
<i>Asset (billion RMB)</i>	Total assets at the beginning of the year when the loan is made, adjusted to constant year 2013 RMBs
<i>Borrower industry median return volatility (%)</i>	The median of the standard deviation of daily return in the borrower industry during the year before the loan is made
<i>Borrower industry sales growth dispersion (%)</i>	The standard deviation of sales growth in the borrower industry during the year before the loan is made
<i>CAR [-5, +5] (%)</i>	The cumulative abnormal return 11 days around the loan announcement, calculated based on the market model, where the estimation period is during trading days [-150, -10], where day 0 is the announcement day
<i>Change of debt (%)</i>	Change of total debt in the year before when the loan is made, divided by the average of assets at the beginning and the end of the year
<i>Collateral</i>	A dummy equal to one if a loan requires collateral, and zero otherwise
<i>Collateral or Guarantee</i>	A dummy equal to one if a loan requires collateral or third-party guarantee, and zero otherwise
<i>Debt/asset (%)</i>	The ratio of total debt to assets at the beginning of the year when the loan is made
<i>Delinquent or overdue or extend dummy</i>	A dummy equal to one if a loan is delinquent, extended or overdue, and zero otherwise
<i>Guarantee</i>	A dummy equal to one if a loan requires third-party guarantee, and zero otherwise
<i>Interbank offered rate (%)</i>	The daily average of China's official interbank offered rate in the year when the loan is made
<i>Loan amount (Million RMB)</i>	The RMB amount of a loan, adjusted to constant year 2013 RMBs
<i>Loan amount/assets (%)</i>	The total loan amount a firm made during a year, divided by firm assets at the beginning of the year when the loan is made
<i>Loan dummy</i>	A dummy equal to one if a firm made a loan in a certain year, and zero otherwise
<i>Maturity (Month)</i>	The maturity of a loan
<i>Ownership</i>	The lender's equity ownership in the borrower (in decimals). This variable is only defined for affiliated loans.
<i>Purpose of loan – debt retirement dummy</i>	A dummy equal to one if the stated purpose of a loan is for debt retirement, and zero otherwise
<i>Purpose of loan – specified project dummy</i>	A dummy equal to one if the stated purpose of a loan is for a specific investment project, and zero otherwise
<i>Real estate borrower</i>	A dummy equal to one if the borrower is in the real estate and construction industry, and zero otherwise
<i>Real estate lender</i>	A dummy equal to one if the lender is in the real estate and construction industry, and zero otherwise
<i>ROA (%)</i>	Return on assets in the year before the entrusted loan is made
<i>Sales growth (%)</i>	The sales growth rate in the year before the entrusted loan is made
<i>Same city</i>	A dummy equal to one if the borrower is in the same city as the lender, and zero otherwise

<i>Same industry</i>	A dummy equal to one if the borrower is in the same industry as the lender, and zero otherwise
<i>SOE borrower</i>	A dummy equal to one if the borrower is a state owned enterprise, and zero otherwise
<i>SOE lender</i>	A dummy equal to one if the lender is a state owned enterprise, and zero otherwise
<i>Trade relationship</i>	A dummy equal to one if the borrower is a customer, or a supplier, or a joint-venture partner of the lender. This variable is only defined for affiliated loans.
